Received 14 June 2012; accepted 7 July 2012

Key indicators: single-crystal X-ray study; $T = 200\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; disorder in main residue; R factor = 0.055; wR factor = 0.124; data-to-parameter ratio = 13.1.

The title compound, $3\text{C}_{10}\text{H}_8\text{N}_4\cdot2\text{C}_7\text{H}_6\text{O}_5\cdot2\text{CH}_4\text{O}$, has a molecular crystal structure which results from the cocrystallization of gallic acid (GA), 4,4'-azodipyridine (AzPy) and methanol in a 2:3:2 molar ratio. The asymmetric unit comprises one molecule each of GA, AzPy and methanol in general positions and half a molecule of AzPy as this is located about a centre of inversion. In the crystal, all the components of the structure are associated via the extended system of hydrogen bonds ($\text{O}-\text{H}\cdots\text{O}$ and $\text{O}-\text{H}\cdots\text{N}$) and $\pi-\pi$ stacking interactions [centroid-centroid distance = $3.637(3)\text{ \AA}$] into two-dimensional supramolecular layers which are packed parallel to the [101] plane. The shortest perpendicular distance and the slippage between aromatic groups are $3.395(3)$ and $2.152(3)\text{ \AA}$, respectively. The AzPy molecules display a *trans* conformation with respect to the azo groups.

Comment

As a part of our research interest in the photosensitive compounds, we report analysis of the crystal structure of the title compound that comprises 1:1.5:1 gallic acid, 4,4'-azodipyridine and methanol molecules. The asymmetric unit of the title compound along with the atom numbering scheme is depicted in Figure 1. Gallic acid has a great potential for structure extension by the three hydroxyl groups and carboxyl function (Fazary *et al.*, 2009). 4,4'-Azodipyridine has been widely used for its bidentate type ligand ability (Zhuang *et al.*, 2006; Kanoo, *et al.*, 2012) and photoswitchable properties (Qiu, *et al.*, 2011). In the crystal all components of the structure are interacting *via* an extended system of O—H—O and O—H—N hydrogen bonds, the formation of which is completely realised. The geometry of the hydrogen bonds is listed in the Table 1. The crystal structure essentially results from the packing of two-dimensional supramolecular layers in parallel orientation to the [101] plane (Figure 2). In addition, each layer is consolidated by π - π stacking interaction, which is evidenced by centroid-to-centroid distance of 3.637 Å between adjacent centrosymmetrically related AzPy rings denoted by C18 C19 C20 C21 C22 and N6 atoms.

Experimental

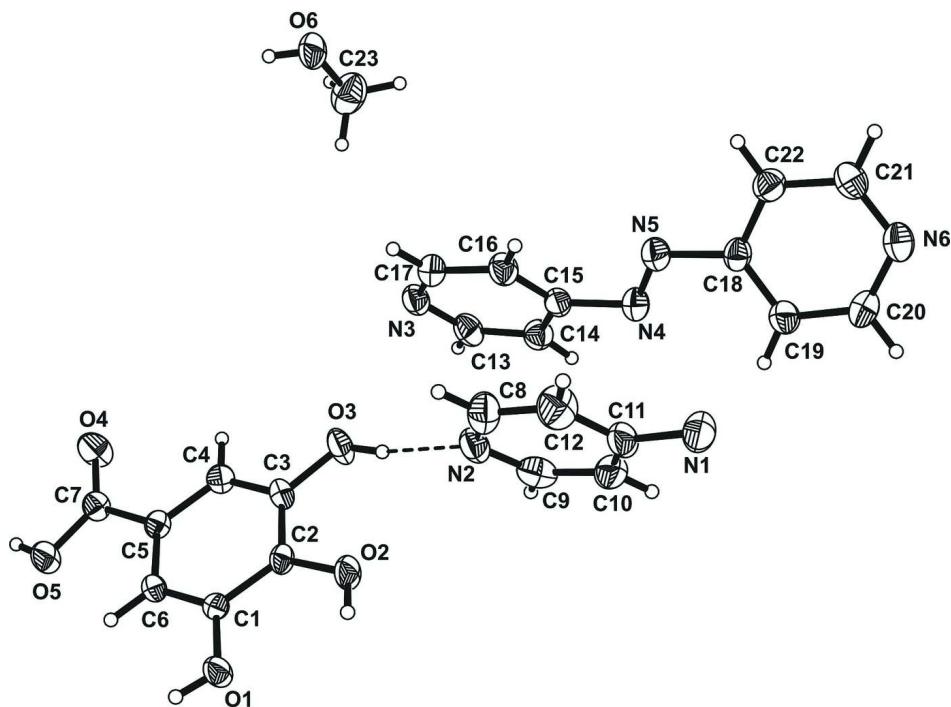

AzPy were synthesized in our laboratory (Launay *et al.*, 1991). Gallic acid (0.085 g, 0.5 mmol) was dissolved in 5.0 ml MeOH and the solution was poured slowly into a methanol solution (5.0 ml) of the synthesized azodipyridine (0.092 g, 0.5 mmol). The resulting mixture was stirred for 30 min and was allowed to stand at room temperature. Slow evaporation for several weeks afforded red block-like crystals.

Refinement

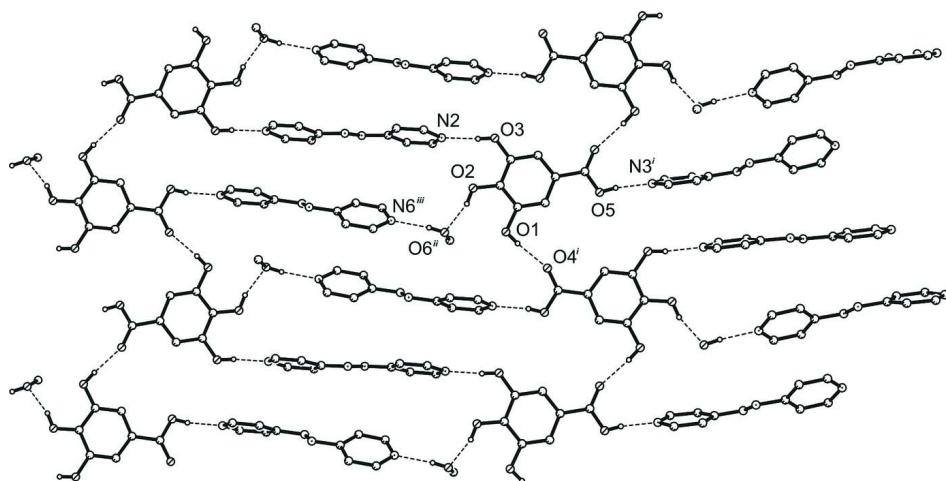

C-bound H-atoms were positioned geometrically and refined using a riding model approximation with C—H = 0.93 Å and $U_{\text{iso}}(\text{H}) = 1.2$ times $U_{\text{eq}}(\text{C})$. The hydroxy H-atoms were located in a difference Fourier map and refined freely. The N1 atom of the centrosymmetric AzPy presented large thermal ellipsoids, so that disordered models, in the combination with the available tools (PART and SADI) of *SHELXL97* were applied in order to better fit the electron density. It was found to be disorderd over two sites in the 0.833:0.167 (8) ratio.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
